

Sebastian Mohr - 23141808 - Part II

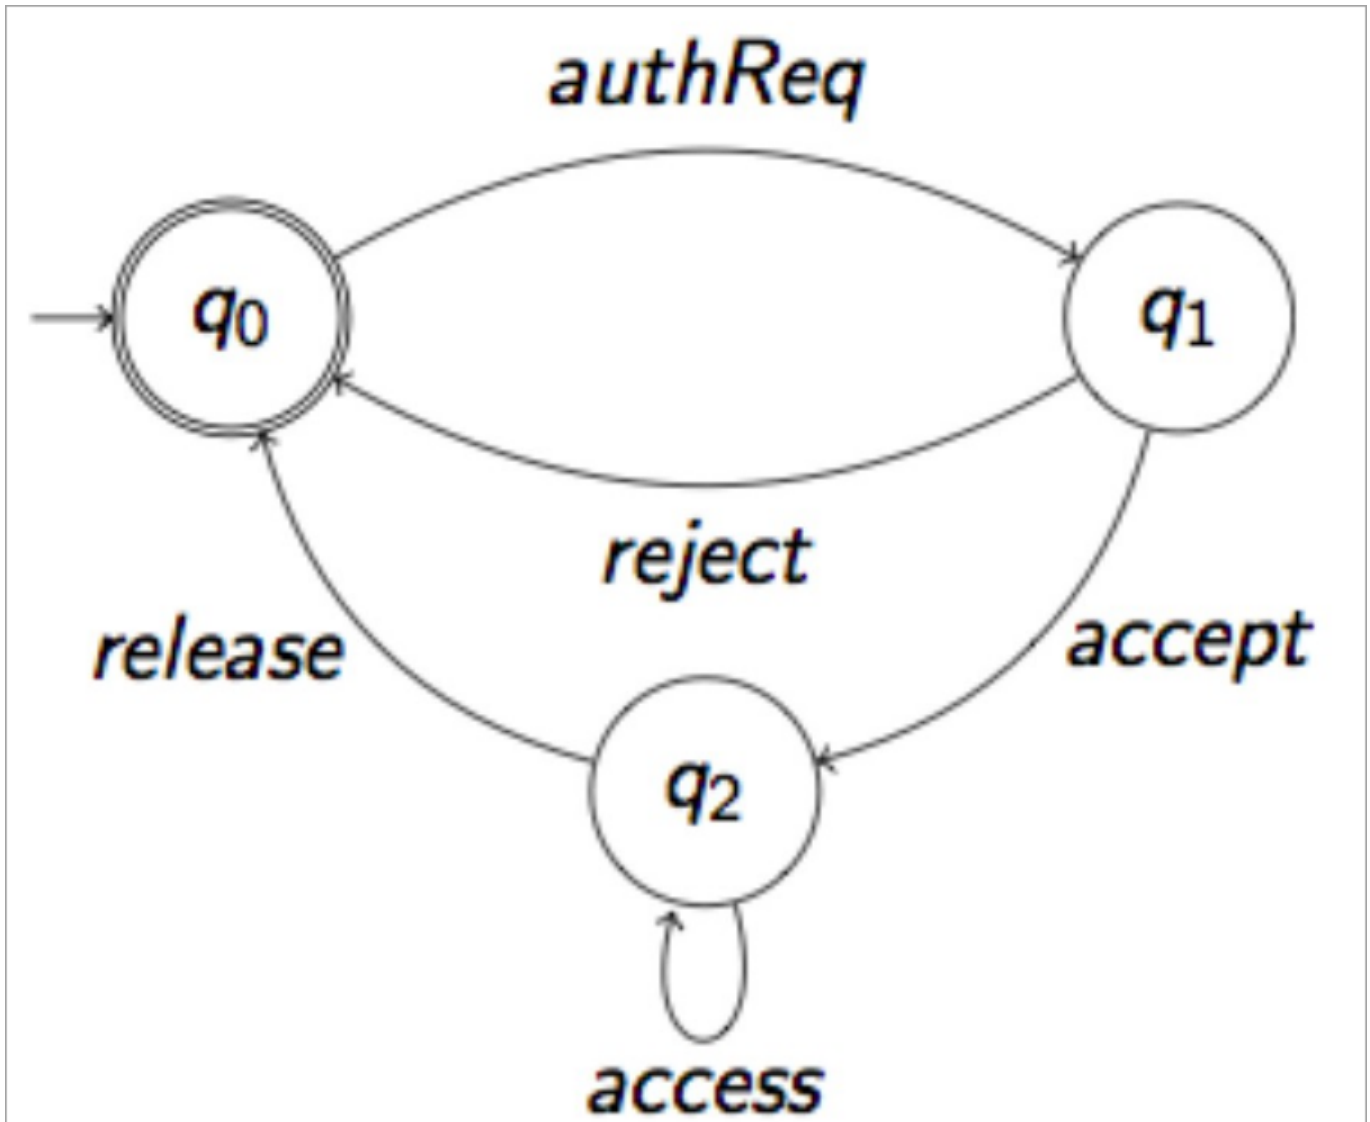

a

$$\omega = (ac * b)^\omega$$

It's an infinite loop, that can starts with the a transformation. Afterwards it can revolve around c or take path b , which brings it back to the state where the next transformation is a .

b

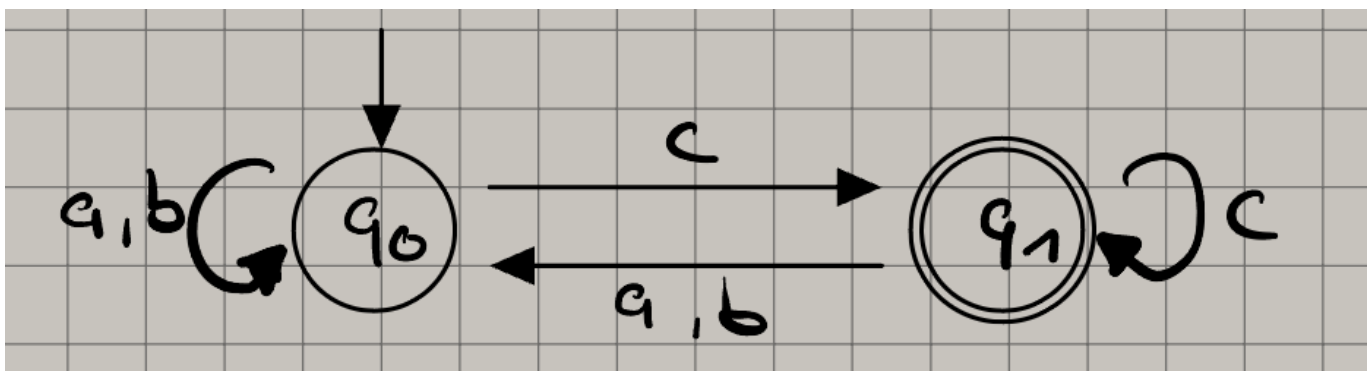

$$\omega = \emptyset + (\text{authReq} (\text{accept access}^* \text{release})) + (\text{authReq reject})^{\omega}$$

To reach the accepted state q_0 , the automaton can take 3 different paths:

1. 0 transitions, start state is accepted state.
2. The transition goes to q_1 and back to q_0 , with authReq and reject each executing once.
3. The transition goes to q_1 with transition authReq . Afterwards it reaches q_2 by executing accept once, then access $0 - \infty$ times. Executes release once to reach final state q_0 .

The automaton is a loop, which means it can execute infinite times.

C

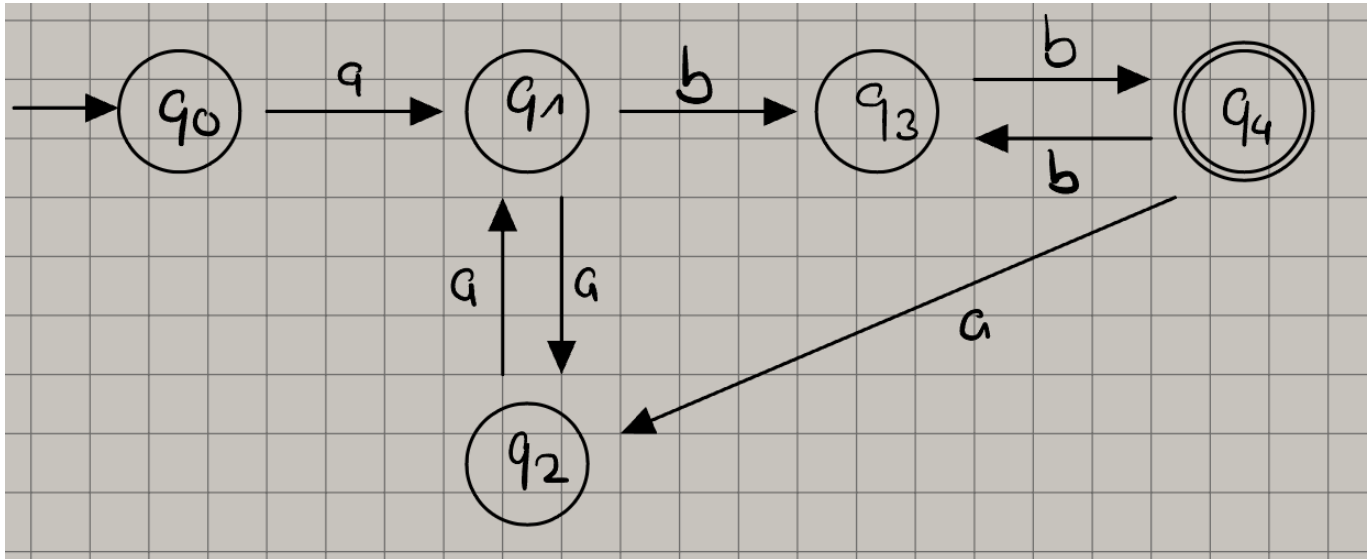

The automaton accepts $\omega = (a * b * c)^\omega$, which translates to:

- $0 - \infty$ times a
- $0 - \infty$ times b
- exactly 1 times c

This process can loop infinite times, that means that the accepting state always has to have a c leading to it.

d

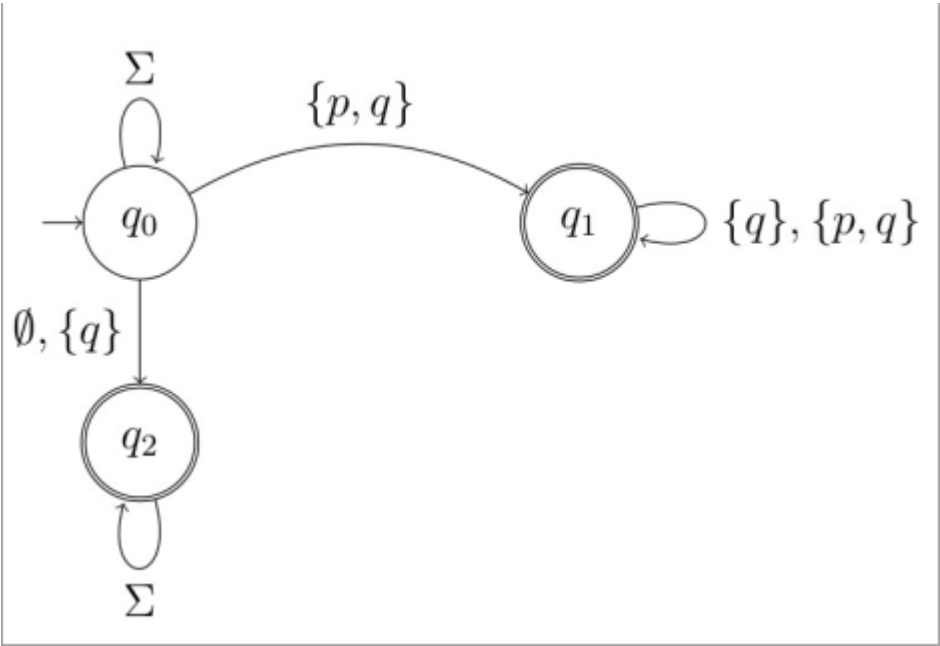

The automaton accepts $\omega = a ((a a) * b b)^\omega$, which translates to:

- exactly 1 a
- and then looping the following:
 - $0 - \infty$ times a and a
 - exactly 1 times b and b

e

LTL-formula: $\neg (p \rightarrow G \neg q)$

Alphabet: $\Sigma := \{\emptyset, \{p\}, \{q\}, \{p, q\}\}$

The given LTL-formula means: in the *Future* p leads to *Globally* q being true

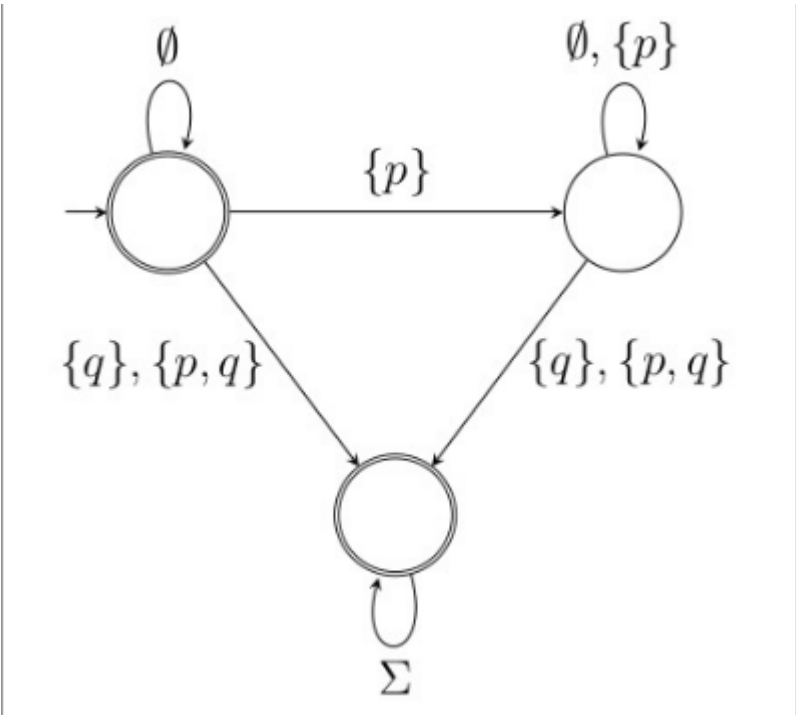

As the automaton switches to the accepted state q_1 when executing p , there is a path that proves the LTL-formula.

Also the automaton can switch to accepted state q_2 when executing q first. There the entire alphabet loops over the state, so the LTL-formula can also be proved.

That means, that the Büchi automaton accepts the runs staisfying the LTL-formula.

f

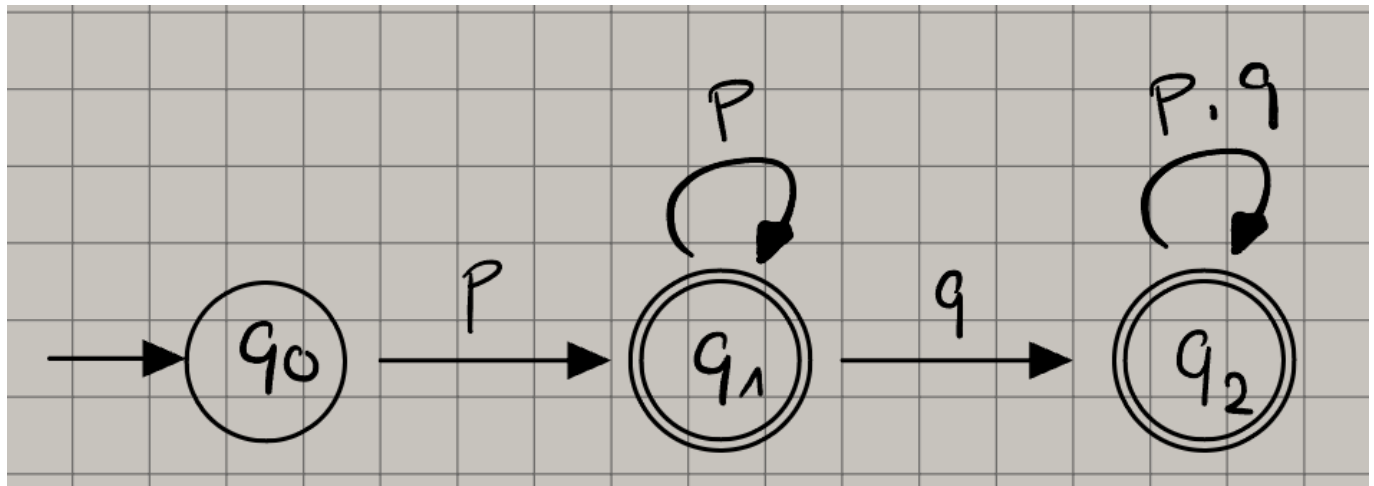

Alphabet: $\Sigma := 2^{\{p, q\}}$

LTL-formula: $\mathcal{G} \neg p \vee \mathcal{U} (q \vee \{p, q\})$

The automaton accepts only p , until at least one q or $\{p, q\}$ is put in. Afterwards the entire alphabet is staying in the accepted state.

g

The automaton accepts $G \neg p \vee F (p \wedge q)$, which translates to:

- Globally p is true, **OR**
- in the *Future* p **AND** q are true
